INF102 Algorithms and Data Structures

Marc Bezem[1]

[1]Department of Informatics
University of Bergen

Fall 2015

INF102

- Lecturer: Marc Bezem, teaching assistants: NN
- Homepage: INF102 (hyperlinks in red)
- Textbook: Algorithms, 4th edition, R. Sedgewick and K. Wayne, Pearson, 2011
- Prerequisites: INF100 + 101 ($\approx$ Ch. 1.1 + 1.2)
- Syllabus (pensum): Ch. 1.3–1.5, Ch. 2, Ch. 3, Ch. 4
- Exam: two or three compulsory exercises and a written exam
- Old exams: 2004–2013, 2014
- Contents of these slides here

Didactical stuff

- ▶ Good textbook from USA: many pages, exercises etc.
- ▶ Average speed must be ca 50 pages p/w
- ▶ Lectures focus on the essentials
- ▶ Prepare yourself by reading in advance
- ▶ Workshops about selected exercises
- ▶ Test yourself by trying some exercises in advance
- ▶ If you can do the exercises (incl. compulsory), you are fine

Generic Bags, Queues and Stacks

- Generic programming in Java, example: PolyPair.java
- Bag, Queue and Stack are generic, iterable collections
- Queue and Stack: Ch. 9 in textbook INF100/1
- APIs include: `boolean isEmpty()` and `int size()`
- All three support adding an element
- Queue and Stack support removing an element (if any)
- FIFO Queue, LIFO Stack
- Dijkstra's Two-Stack Expression Evaluation Movie

Implementations

- ResizingArray_Stack.java
- Resizing takes time and space proportional to size
- LinkedList_Stack.java
- Pointers take space and dereferencing takes time
- Programming with pointers: make a picture
- LinkedList_Queue.java

Computation time and memory space

- ▶ Two central questions:
  - ▶ How long will my program take?
  - ▶ Will there be enough memory?
- ▶ Example: TheeSum.java
- ▶ Inner loop is important

Methods of Analysis

- Empirical:
  - Run program with randomized inputs, measuring time & space
  - Run program repeatedly, doubling the input size
  - Measuring time: StopWatch
  - Plot, or log-log plot and linear regression
- Theoretical:
  - Define a cost model by abstraction (e.g., array accesses, comparisons, operations)
  - Try to count/estimate/average this cost as function of the input (size)
  - Use $O(f(n))$ and $f(n) \sim g(n)$

ThreeSum, empirically

- ▶ Input sizes 1K, 2K, 4K, 8K take time 0.1, 0.8, 6.4 ,51.1 sec
- ▶ The log's are 3, 3.3, 3.6, 3.9 and -1, -0.1, 0.8, 1.71
- ▶ Linear regression gives $y \approx 3x - 10$
- ▶ $\lg(f(n)) = 3\lg(n) - 10$ iff

$$f(n) = 10^{\lg(f(n))} = 10^{3\lg(n)-10} = n^3 * 10^{-10}$$

- ▶ Conclusion: cubic in the input size, with constant $\approx 10^{-10}$
- ▶ Strong dependence on input can be a problem
- ▶ Constant 10^{-10} depends on computer, exponent 3 does not

ThreeSum, theoretically

- ▶ Number of different picks of triples: $g(n) = n(n-1)(n-2)/6$
- ▶ Inner loop executed $g(n)$ times
- ▶ $g(n) = n^3/6 - n^2/2 + n/3$
- ▶ Cubic term $n^3/6$ wins for large n
- ▶ Computational model # array accesses: $n^3/2$
- ▶ Cost array access t sec: time $t * n^3/2$ sec
- ▶ Cost models are abstractions! (NB cache)

Big Oh, and $\sim$

- Q: 'wins for large n' uhh???
- A: Big Oh, and $\sim$ will clear this up
- Costs are positive quantities, so $f, g, \dots : \mathbb{N} \to \mathbb{R}^+$
- MNF130: $f(n)$ is $O(g(n))$ if there exist c, N such that $f(n) \leq cg(n)$ for all $n \geq N$
- Example: n^2 and even $99n^3$ are $O(n^3)$, but n^3 is not $O(n^{2.9})$
- INF102: $f(n) \sim g(n))$ if $1 = \lim f(n)/g(n)$
- If $f(n) \sim g(n))$, then $f(n)$ is $O(g(n))$ and $g(n)$ is $O(f(n))$
- Big Oh and $\sim$ aim to capture 'order of growth'
- Big Oh abstracts from constant factors, $\sim$ does not
- Large constant factors are important!

Important orders of growth

- constant: c ($f(n) = c$ for all n)
- linear: n (compare all for $n = 20$ sec)
- linearithmic: $n \lg n$
- quadratic: n^2
- cubic: n^3
- exponential: 2^n
- general form: $an^b(\lg n)^c$

Examples

- ▶ Worst case: guaranteed, independent of input
- ▶ Average case: not guaranteed, dependent of input *distribution*
- ▶ Linked list implementations of Stack, Queue and Bag: all operations take constant time in the worst case
- ▶ Resizing array implementations of Stack, Queue and Bag: adding and deleting take linear time in the worst case (easy)
- ▶ Resizing array implementations of Stack, Queue and Bag: adding and deleting take on average constant time in the worst case (difficult)
- ▶ Special case of resizing array that is only growing: 1(2)2(4)34(8)5678(16)9 ... 16(32) ..., with (n) the new size. Risizing to (n) costs $2n$ array accesses, so in total $(1+4)+(1+8)+(2+16)+(4+32)+(8+64)$ ..., so 9 per push.

Staying Connected

- MNF130: relation $R \subseteq V \times V$ is an *equivalence* if
  - R is *reflexive*: $\forall x \in V.\ R(x, x)$
  - R is *symmetric*: $\forall x, y \in V.\ R(x, y) \rightarrow R(y, x)$
  - R is *transitive*: $\forall x, y, z \in V.\ R(x, y) \wedge R(y, z) \rightarrow R(x, z)$
- We assume connectedness to be an equivalence
- Dynamic connectivity means that R can grow and shrink
- Example: if the 'Bergensbanen' is broken, Oslo and Bergen are no longer connected by rail
- We want efficient algorithms and datastructures for testing whether two objects are connected
- Clear relationship with paths in graphs, more in Ch. 4
- Here we take $V = \{0, \ldots, N - 1\}$.

Staying Connected

- MNF130: relation $E \subseteq V \times V$ is an *equivalence* if
  - E is *reflexive*: $\forall x \in V. \, E(x,x)$
  - E is *symmetric*: $\forall x, y \in V. \, E(x,y) \to E(y,x)$
  - E is *transitive*: $\forall x, y, z \in V. \, E(x,y) \wedge E(y,z) \to E(x,z)$
- We assume connectedness to be an equivalence
- Dynamic connectivity means that R can grow and shrink
- Example: if the 'Bergensbanen' is broken, Oslo and Bergen are no longer connected by rail
- We want efficient algorithms and datastructures for testing whether two objects are connected
- Clear relationship with paths in graphs, (connected) components (MNF130)
- We take $V = \{0, \ldots, N-1\}$.

Union Find

- UF, idea: every component has an identifier ('hub'), which has edges ('spokes') to the elements of its component
- API: UF
- Implementations with `int[] id` containing the identifiers
  - SlowUF.java
  - FastUF.java
  - WeightedUF.java
- WeightedUF: log depth of tree (Proposition X)

Sorting

- Sorting: putting objects in a certain order
- MNF130: relation $R \subseteq V \times V$ is a *total order(ing)* if
  1. R is *reflexive*: $\forall x \in V.\ R(x,x)$
  2. R is *transitive*: $\forall x, y, z \in V.\ R(x,y) \land R(y,z) \rightarrow R(x,z)$
  3. R is *antisymmetric*: $\forall x, y \in V.\ R(x,y) \land R(y,x) \rightarrow x = y$
  4. R is *total*: $\forall x, y \in V.\ R(x,y) \lor R(y,x)$
- Natural orderings:
  - Numbers of any type: ordinary $\leq$ and $\geq$
  - Strings: lexicographic
  - Objects of a Comparable type: `v.compareTo(w) < 0`

Sorting (ctnd)

- Bubble sort: ExampleSort.java
- Certification: `assert isSorted(a)` in `main()`
- No guarantee against modifying the array (but `exch()` is safe)
- Costmodel 1: number of `exch()`'s and `less()`'s
- Costmodel 2: number of array accesses
- Pitfalls: cache misses, expensive `v.compareTo(w) < 0`
- Why studying sorting? (`java.util.Arrays.sort()`)
- Comparing sorting algorithms: CompareSort.java

Selection Sort

- Bubble sort: $\sim n^2/2$ compares, $0 \ldots \sim n^2/2$ exchanges
- Selection sort:
  - Find index of a minimal value a[1..n], exchange with a[1]
  - Find index of a minimal value a[2..n], exchange with a[2]
  - ... until n-1
- Selection sort: $\sim n^2/2$ compares, $n-1$ exchanges

```
public  static void sort(Comparable[] a) {
 int N = a.length;
 for (int i=0; i<N-1; i++){
   int min=i;
   for (int j=i+1; j<N; j++) if less(a[j],a[min])) min=j;
   exch(a,i,min);
 }
 }
```

Insertion sort

- ▶ Insertion sort:
  - ▶ Insert a[2] on its correct place in (sorted) a[1..1]
  - ▶ Insert a[3] on its correct place in (sorted) a[1..2]
  - ▶ ... until a[n]
- ▶ Very good for partially sorted arrays, costs:
  - ▶ Best case: $n-1$ compares and 0 exchanges
  - ▶ Worst case: $\sim n^2/2$ compares and exchanges
  - ▶ Average case: $\sim n^2/4$ compares and exchanges (distinct keys)

```
public  static void sort(Comparable[] a) {
 int N = a.length;
 for (int i=1; i<N; i++){
  for (int j=i; j>0 && less(a[j],a[j-1]); j--)
    exch(a,j,j-1);
 }
}
```

Shell sort

- Insertion sort:
    - Very good for partially sorted arrays
    - Slow in transport: step by step `exch(a,j,j-1)`
- Idea: h-sort, `a[i]`,`a[i+h]`,`a[i+2h]`,... sorted (any `i`)

```
public static void hsort(int h, Comparable[] a) {
 int N = a.length;
 for (int i=h; i<N; i++)
  for (int j=i; j-h>=0 && less(a[j],a[j-h]); j-=h)
    exch(a,j,j-h);
}
```

- Insertion sort: `hsort(1,a)`
- Shell sort: e.g., `hsort(10,a); hsort(1,a)`

Shell sort (ctnd)

- ▶ hsort(10,a); hsort(1,a) faster than just hsort(1,a) !
- ▶ Q: How is this possible?
- ▶ A: hsort(10,a) transports items in steps of 10, which would be done by hsort(1,a) in 10 steps of 1
- ▶ What about hsort(100,a); hsort(10,a); hsort(1,a)?
- ▶ To be expected: depends on the length N of the array
- ▶ Book:

Mergesort

- Recursive algorithm:
  - Mergesort left half, mergesort right half
  - Merge the results
- Merge Movie

Merge (code)

```
public static void merge(Comparable[] a,  int lo, int m, i
 for (int k=lo; k<=hi;k++) aux[k] = a[k];
 int l = lo, r = m+1;
 if (l>m) {a[k] = aux[r++]; break;}
 if (r>hi) {a[k] = aux[l++]; break;}
 if less(a,l,r) {aux[l++];} else {aux[r++];} // max N compa
 }
```

ToC and topics of general interest

- Table of Contents on next slide (all items clickable)
- Practical stuff: slide 2
